54 A shock-proof protective jacket for portable instruments, particularly for remote control units.

57 The protective anti-shock jacket (1) for instruments (2) for personal and professional use, in particular for portable remote control units, is of the structurally monolithic type made in elastomer material, and exhibits in its inferior wall 8 one or more windows or slits (9, 10) destined to reduce tension on the other walls, which tension is relative to the elastic reaction of the material of the elastically deformed jacket, with the insertion of the said instrument (2) into the jacket (1).

The invention relates to a shock-proof protective jacket, particularly suitable for portable remote instruments and in general remote-control units, such as for example portable telephones, alarm clocks, professional instruments such as calculators, measuring instruments and suchlike.

The follow description will make special reference to portable remote control units of the above-specified type; the jacket in question, however, may find application also in other types of instrument.

The problem of protecting such remote control units from shocks and bumps has already been dealt with in the art and has been adequately solved by providing a by now well-known jacket which in Italy goes by the trade-mark name of "Guscio TV", produced and sold by the present applicant and object of Industrial Invention Patent no. 1,208,461.

The solution according to the above-mentioned patent solves the problem of remote-control unit protection by providing a jacket in elastomer material having a substantially parallelepiped shape, and having also internal dimensions which are substantially similar to the external dimensions of the instrument to be inserted and protected, the said jacket also being of a thickness which is sufficient to absorb shocks. The realisation of the said jacket, even if it is structured in such a way as to be considerably elastic, has one limitation relative to the need to produce a rather large number of different jackets in order to meet the different size requirements of various remote control units.

The applicant felt that the practice of having jackets which are structurally defined according to the requirements of specific shapes of instruments to be protected would be better abandoned in favour of jackets which were each suitable for single units within groups of instruments having quite different shapes.

The aim of the present invention is therefore to make a jacket in elastomer material with good elastically-deformable characteristics, particularly suitable for remote control units with quite varied shapes, especially, but not exclusively, with regard to their length.

To reach the said aim, the applicant has invented a jacket in one-piece elastically-deformable material, having, in substance, six walls, one of which being superior with at least one large window for the insertion of the instrument and for external access to the said instrument, one inferior, two at the ends and two lateral sides, and having in the said inferior wall, one or more windows or slits to reduce the tension on the said inferior wall and on the other walls, a tension which is due to the reaction of the deformed material to the insertion of the said instrument into the jacket, thus permitting a good adherence of the jacket to the instrument without incurring unwanted deformation of the most stretchable parts of the jacket itself, which

would suffer most from such tensions.

These and other characteristics of the invention will be described in more detail in the description which follows, with the help of the accompanying illustrations which represent some purely exemplary and non-limiting embodiments for portable remote control units, and in which :

- Figure 1 shows the jacket in plan view;
- Figure 2 shows the jacket in a view from below;
- Figure 3 is a partial horizontal flat section of the jacket passing through axis III-III indicated in figure 1 and with the instrument also partially illustrated in inserted position;
- Figure 4 is a partial horizontal flat section of the jacket passing through line III-III indicated in figure 1 and relative to an alternative embodiment of the jacket;
- Figure 5 is a transversal section of the jacket according to section V-V of figure 1;
- Figure 6 illustrates the jacket in longitudinal section according to line VI-VI of figure 1 and according to an embodiment variant which can be effected in the case of instruments or portable remote control units with one end substantially cusp-shaped or in any case tapered;
- Figure 7 illustrates, partially and in longitudinal section, the head of the jacket illustrated on the left in figure 6 according to a further possible embodiment;
- Figures 8 and 9 are partial horizontal flat sections of the jacket according to a possible embodiment variant with respect to what is illustrated in figures 3 and 4.

With particular reference to figure 1, the jacket object of the invention takes the form of a sheath 1 of substantially parallelepiped shape, into which a remote control unit or an instrument 2 can be inserted through an opening 3 made in the jacket's superior wall 4, which superior wall 4 function is also that of permitting user access to the buttons or the operative panel of the instrument housed in the jacket.

The jacket can be made by pressing of an elastomer material, for example a polyurethane, having considerably elastic characteristics, as indicated hereinafter, and in one or more portions of the lateral walls or sides 5 and of the superior wall 4 and the inferior wall 8 adjoining the sides 5, the sheath or jacket 1 has according to a longitudinal section, areas of greater thickness 13 connected to and alternated with areas of lesser thickness 14. This alternation creates portions of greater elastic compliance for an easier elastic deformation of the jacket 1.

Alternatively, as is illustrated in figure 4, on the said portions, or in any case comprised between the two ends, the jacket 1 can have a longitudinal section 15 conformed according to a bellows-shape to favour a considerable elastic extension of the jacket 1 in the direction of its longer side.

In both cases, and according to a preferred embodiment, at least the internal surfaces of the sides 5 which connect the inferior wall 8 with the covering or superior wall 4 are connected in such a way as to avoid the presence of sharp edges (see figure 5). Furthermore, and in both cases, again according to a preferred embodiment, the said areas of greater thickness or, respectively, the external peaks of the bellows, are more external with respect to the ends of the jacket 1 with the aim of better ensuring the housed instrument protection against lateral shocks.

For this aim and also with the aim of better stabilising the instrument between the sides of the jacket 1, one or more flexible flaps 18 can be provided internally to the said sides 5 (see figures 8 and 9), which flaps 18 project towards the inside of the jacket 1 and are preferably inclined with respect to the longitudinal centre line of the jacket 1. The above-mentioned flaps 18 can be of one piece with the jacket 1 and be obtained during the pressing operation.

Windows or slits 9 and 10 are cut into the inferior wall 8 and preferably develop parallel to the sides 5 and respectively to the end walls 6 of the jacket 1.

When the jacket 1 is used to cover an instrument having dimensions somewhat larger than those of the inside of the jacket 1, the said slits 9 and 10 stretch elastically and reduce the tension on the other walls, which tension is due to the elastic reaction of the deformed material on the insertion of the remote control unit into the jacket 1; in this way the wrapping of the jacket 1 around the remote control unit is achieved without undesired deformation of the most compliant portions of the jacket 1, on which such tensions would normally act, especially in proximity to the edge 12 of the opening 3 in the superior wall 4, through which the instrument is inserted into the jacket 1.

The slits 9 and 10 can be closed up with a thin film in the same material as the jacket 1 and produced during the pressing of the same, the said film being of no importance as far as the reasons for having the said slits 9 and 10 are concerned.

Further, with the aim of avoiding splits during the elastic extension phase of the jacket 1, the edges of the said slits 9 and 10 can have slightly reinforcing swellings and thus no sharp edges.

According to a preferred embodiment of the invention and once again in order to avoid unwanted deformation, the edge 12 around the opening 3 can have a reinforcement swelling which contributes to greatly limiting, at least with regard to the longitudinal sides, the effects of the said elastic reaction of the material due to the insertion of the instrument in the jacket 1. In order to avoid any eventual difficulty caused, by the said swelling with respect to accessibility to the command buttons situated on the instrument panel and nearest to the said edge 12, the edge 12 exhibits, in section, a back draft going from the outside towards the inside, as illustrated in figure 5.

Still according to a preferred embodiment, the body of the jacket 1, at the sides 5 which connect its two ends destined to wrap elastically around the ends of the instrument, has a thickness in the stretchable areas which is less than that of the said ends. Furthermore, the intermediate part of the inferior wall 8 less thick than the peripheral frame 8' in which the slits 9 and 10 are made: this favours to the full the stretchability of the body of the jacket 1. In the case herein described, at least one end wall 6 of the jacket 1 exhibits a second opening 7, necessary to permit the transmitting of signals emitted by the remote control device to the outside (see, for example, figure 9).

In this case the use of a particularly elastic material, in particular for cusp-headed or tapered remote control units, could bring about an unwanted deformation of the said end wall 6 due to the interaction of the said cusp-shaped head on a small part of the head of the jacket 1 enveloping the said second opening 7. In this case, and according to a possible embodiment of the jacket 1 object of this invention, illustrated in figure 6, at the said second opening 7 a flat element 16 is envisaged, which flat element 16 is bend-resistant but transparent to the signals or impulses emitted by the instrument and interpositionable between the end of the said instrument which emits the signals and substantially the entire surface of the internal face of the wall of the end walls 6 in which the said second opening 7 is present.

This rigid and substantially flat element 16, which can be made in plexiglas or similar materials, distributes evenly the reaction of the jacket 1 body over all of the internal periphery of the end wall 6 in contact with it, which reaction is consequent to the elastic deformation necessary for the introduction of the instrument into the jacket 1 itself. For the stable positioning of the said flat element 16, the jacket 1 has a peripheral groove 17 sunk during the pressing phase into the internal surface of the end wall 6, into which peripheral groove 17 the peripheral edge of the said flat element 16 can be inserted by means of elastic deformation of the parts of the jacket 1 near to the said peripheral groove 17.

According to a further embodiment (see figure 7), the peripheral groove 17 can be obtained during the pressing phase of the jacket 1 between the said internal surface of the end wall 6 having the second opening 7 and one or more ridges 11 facing the said internal surface.

The said ridges 11 have a substantially saw-tooth section and their side nearest the end wall 6 is parallel to it. With this conformation it is possible to introduce the flat element 16 into the peripheral groove 17 by sliding it up the inclined faces of the ridges 11.

As indicated above, the jacket 1 can be made by pressing of an open-celled material, for example polyurethane.

It has been shown experimentally that a material

which is particularly suited for the jacket 1 is micro-cellular polyurethane pressed with 0.4 g/cm³ pressing density the choice of the components, taken from the isocyanates and the polyhydric alcohol families, for the polyurethane is important in order to obtain the following mechanical characteristics for the body of the jacket 1:

- hardness of the pressed object, Shore A from 3 to 70;
- maximum tensile stress from 6 to 50 kg/cm²;
- stretching from 200 to 250%;
- tearing resistance from 1.2 to 6 kg/cm;
- abrasion (DIN 53516) from 350 to 150 g.;
- compressive strength from 0.4 to 7.5 kg/cm²;

Thanks to these characteristics, together with those deriving from its actual structure, the jacket 1 object of the invention is easily elastically stretchable lengthwise, widthwise and heightwise and can be used to remote control units or instruments of differing shapes and sizes.

Obviously in practice all of the above-described details could be substituted by technically equivalent elements or materials.

For example, especially the slits 10 could be elliptical in shape, or circular or polygonal. Also the slits 9 and 10 could be substituted by a succession of small windows or holes providing practically the same technical effect as the slits herein-described and illustrated.

The above-mentioned holes could be arranged in two close lines with those in one of the lines being intercalated between those of the nearby lines.

Claims

1. A shock-proof protective jacket for personal and professional instrument, in particular for portable remote-control units of the single-body type made in elastomer material and having six walls, one of which being superior with at least one large window for the insertion of the instrument and for external access to the said instrument, one inferior, two at the ends and two lateral sides defining the sides of the jacket (1), and at least one window or opening (3) made in the superior wall (4) to afford access to the instrument (2) from the outside, characterised by the fact of having in the inferior wall (8) one or more windows or slits (9) and (10) in proximity to at least one end wall (6) and sides (5) which slits (9) and (10) have the function of reducing also on the other walls the tension relative to the elastic reaction of the jacket material which is elastically deformed with the insertion of the said instrument (2) into the jacket (1).

2. A protective jacket as in claim 1, characterised by

the fact that in one or more portions of the said lateral sides (5), or in the whole lateral sides (5) intermediate part, comprised between the two ends (6) of the jacket (1), and in one or two contiguous portions of the superior wall (4) and the inferior wall (8), there are areas of greater thickness (13) connected and alternated with areas of lesser thickness (14).

3. A jacket as in claim 1, characterised by the fact that in one or more portions of the lateral walls or sides (5) or in the whole intermediate part of the said sides (5) comprised between the two ends (6) of the jacket (1), and in one or more contiguous portions of the superior wall (4) and the inferior wall (8), there is a longitudinal section conformed in a bellow shape (15).

4. A jacket as in claim 1, characterised by the fact that the edge (12) of the said opening (3) and the said slits (9 and 10) edge exhibit a swelling or reinforcement along at least their longer sides, and characterised by the fact that the said edges do not exhibit sharp edges.

5. A jacket as in claim 4, characterised by the fact that the said edge (12) exhibits in section a back draft going from the outside towards the inside, with a thinning towards the inside and at least on its longitudinal tracts.

6. A jacket as in claim 1, characterised by the fact that the said slits (9 and 10) are closed by a thin film of the same material as the jacket (1) itself, which film is obtained during the production by pressing of the said jacket (1).

7. A jacket as in claims 1, 2 or 3, characterised by the fact that the said sides (5) stretchable areas are of lesser thickness with respect to the thickness of the ends (6) of the jacket (1).

8. A jacket as in claim 1, characterised by the fact that the said inferior wall (8) intermediate part is of lesser thickness with respect to a perimetral frame of the same inferior wall (8) connected with the sides (5) of the jacket (1) and that the said slits (9) and (10) are made in the said intermediate part.

9. A jacket as in the preceding claims, characterised by the fact of having in at least one of its two ends (6) a second opening (7) for the transmission to the outside of signals emitted by a remote control unit housed in the said jacket (1).

10. A jacket as in claim 9, characterised by the fact that a flat element (16) is provided at the said

second opening (7), which flat element (16) is resistant to bending and transparent to the signals or impulses emitted by the said instrument, stably interpositionable between one end of the said instrument (2) whence the signals are emitted and substantially the peripheral part of the internal face of the end wall (6) containing the said second opening 7. 5

11. A jacket as in claim 10, characterised by the fact that it exhibits a peripheral groove (17) sunk into the internal surface of the end wall (6) exhibiting the said second opening (7) and destined to hold in place the said flat element (16) perimetral edge. 10 15

12. A jacket as in claim 10 characterised by the fact that, for the stable positioning of the said flat element (16), ridges (11) are provided inside the jacket (1) and are arranged facing the internal surface of the end wall (6) exhibiting the said second opening (7), said ridges (11) having substantially tooth-shaped section and having also their face which is closest to the said end wall (6) parallel to it. 20 25

13. A jacket as in claim 1 or 2 or 3, or 9, characterised by the fact that it exhibits on the internal surface of it sides (5) at least one flap (18) projecting towards the inside of the said jacket (1) for a short tract and preferably inclined with respect to the longitudinal centreline of the jacket (1). 30

14. A jacket, as in claim 1, characterised by the fact that the said slits (9) and (10) exhibit any geometrical shape. 35

15. A jacket, as in claim 1, characterised by the fact that the said slits (9) and (10) are determined by a number of windows or small slits or holes aligned in one or more lines. 40

16. A jacket as in claim 1 or 9, characterised by the fact that the said elastomer material is a microcellular polyurethane pressed with 0.4 g/cm³ pressing density; the choice of the components, taken from the isocyanates and the polyhydric alcohol families, in order to obtain the following mechanical characteristics for the body of the jacket (1): 45 50

- hardness of the pressed object, Shore A from 3 to 70;
- maximum tensile stress from 6 to 50 kg/cm²;
- stretching from 200 to 250%;
- tearing resistance from 1.2 to 6 kg/cm; 55
- abrasion (DIN 53516) from 350 to 150 g.;
- compressive strength from 0.4 to 7.5 kg/cm².
